## List of Tables

4.1.1 Hospital Characteristics . . . . .	11
4.2.1 HAIs Statewide . . . . .	12
4.2.2 HAIs by Type . . . . .	12
4.2.3 HAIs with Methicillin Resistant <i>Staphylococcus aureus</i> by Type . . . . .	13
4.2.4 HAIs and Crude Infection Rates by Facility . . . . .	14
4.3.1 CAUTIs Statewide . . . . .	46
4.3.2 CAUTIs and Device Utilization Rates by Location (within Facility) . . . . .	47
4.3.3 CAUTIs by Pathogen . . . . .	51
4.3.4 Facilities with Significantly Fewer CAUTIs than Predicted (Better = Smaller SIR) . . . . .	53
4.3.5 Facilities with Significantly More CAUTIs than Predicted (Worse = Larger SIR) . . . . .	54
4.3.6 Facilities Omitted from CAUTI SIR Analysis . . . . .	55
4.3.7 CAUTIs and Standardized Infection Ratios (SIRs) by Facility . . . . .	56
4.4.1 Reporting Locations Among Facilities with Central Line Days . . . . .	92
4.4.2 CLABSIs Statewide . . . . .	94
4.4.3 CLABSIs and Device Utilization Rates by Location (within Facility) . . . . .	95
4.4.4 CLABSIs by Pathogen . . . . .	100

4.4.5	Hospitals with Significantly Fewer CLABSIIs than Predicted (Better = Smaller SIR) . . . . .	102
4.4.6	Hospitals with Significantly More CLABSIIs than Predicted (Worse = Larger SIR) . . . . .	102
4.4.7	Hospitals Omitted from CLABSI SIR Analysis . . . . .	103
4.4.8	ICUs and Wards: CLABSIIs and Standardized Infection Ratios (SIRs) By Facility . . . . .	104
4.4.9	NICUs: CLABSIIs and Standardized Infection Ratios (SIRs) By Facility . . . . .	129
4.4.10	SCAs: CLABSIIs and Standardized Infection Ratios (SIRs) By Facility . . . . .	136
4.4.11	LTACs: CLABSIIs and Standardized Infection Ratios (SIRs) By Facility . . . . .	141
4.5.1	SSIs Summary . . . . .	156
4.5.2	SSIs by Pathogen . . . . .	157
4.5.3	SSIs by Benchmarked Procedure and Risk Index . . . . .	159
4.5.4	SSIs Hospital Performance . . . . .	162
4.5.5	Hospitals Omitted from SSI SIR Analysis . . . . .	164
4.5.6	Hospitals with Significantly Fewer SSIs than Predicted (Better = Smaller SIR) . . . . .	166
4.5.7	Hospitals with Significantly More SSIs than Predicted (Worse = Larger SIR) . . . . .	167
4.5.8	SSIs — Cardiac Procedures, SIRs by Hospital . . . . .	168
4.5.9	SSIs — Coronary Bypass (Two Incision) Procedures, SIRs by Hospital . . . . .	180
4.5.10	SSIs — Coronary Bypass (One Incision) Procedures, SIRs by Hospital . . . . .	190
4.5.11	SSIs — Knee Arthroplasty, SIRs by Hospital . . . . .	200
4.5.12	SSIs — Hip Arthroplasty, SIRs by Hospital . . . . .	225
4.5.13	SSIs — Abdominal Hysterectomy, SIRs by Hospital . . . . .	249
4.5.14	SSIs — Colon Surgery, SIRs by Hospital . . . . .	272
4.5.15	SSIs — SIRs for Each Procedure by Hospital . . . . .	287
4.6.1	Summary of HCP Influenza Vaccination Rates . . . . .	313
4.6.2	Hospitals with Seasonal Influenza Vaccination Rate of 90 Percent or Better . . . . .	317
4.6.3	Influenza Vaccination Rates Among HPC By Facility . . . . .	320

## List of Figures

4.3.1	Facility Ranking by CAUTI SIR (Grouped by Number of Predicted Infections: <1) . . . . .	86
4.3.2	Facility Ranking by CAUTI SIR (Grouped by Number of Predicted Infections: 1–2.99) . . . . .	87
4.3.3	Facility Ranking by CAUTI SIR (Grouped by Number of Predicted Infections: 3–7.49) . . . . .	88
4.3.4	Facility Ranking by CAUTI SIR (Grouped by Number of Predicted Infections: 7.5–14.99) . . . . .	89
4.3.5	Facility Ranking by CAUTI SIR (Grouped by Number of Predicted Infections: 15–29.99) . . . . .	90
4.3.6	Facility Ranking by CAUTI SIR (Grouped by Number of Predicted Infections: > 30) . . . . .	91
4.4.1	CLABSI by Unit Type and Year . . . . .	93
4.4.2	CLABSI Reported from SCA Among Patients with Permanent and Temporary Central Lines . . . . .	99
4.4.3	ICUs and Wards: Facility Ranking by CLABSI SIR (Predicted Infections: 0–0.29) . . . . .	145
4.4.4	ICUs and Wards: Facility Ranking by CLABSI SIR (Predicted Infections: 0.5–0.99) . . . . .	146
4.4.5	ICUs and Wards: Facility Ranking by CLABSI SIR (Predicted Infections: 1–2.99) . . . . .	147
4.4.6	ICUs and Wards: Facility Ranking by CLABSI SIR (Predicted Infections: 3–7.49) . . . . .	148
4.4.7	ICUs and Wards: Facility Ranking by CLABSI SIR (Predicted Infections: >= 7.5) . . . . .	149
4.4.8	LTACs: Facility Ranking by CLABSI SIR . . . . .	150
4.4.9	NICUs: Facility Ranking by CLABSI SIR (Predicted Infections: < 1) . . . . .	151
4.4.10	NICUs: Facility Ranking by CLABSI SIR (Predicted Infections: >= 1) . . . . .	152
4.4.11	SCAs: Facility Ranking by CLABSI SIR (Predicted Infections: < 7.5) . . . . .	153
4.4.12	SCAs: Facility Ranking by CLABSI SIR (Predicted Infections: >= 7.5) . . . . .	154
4.6.1	Distribution of Facility HCP Influenza Vaccination Rates by Worker Type . . . . .	314
4.6.2	Distribution of Facility HCP Influenza Vaccination Rates Among 25 Largest Facilities . . . . .	315
4.6.3	Map Employee Influenza Vaccination Rates by Facility . . . . .	316

# 1 Executive Summary

**Overview** The 2015 report on the occurrence and patterns of healthcare-associated infections (HAIs) is the eighth to be released by the Pennsylvania Department of Health (PADOH). Overall, the incidence of HAIs has declined since the 2007 amendment of the MCARE Act (Act 52 of 2007). Legislation known as Act 52 was passed and enacted in 2007 that contains the most comprehensive reporting requirements of any state. The act requires PADOH to collect information on all inpatient HAIs, summarize the findings and publicly report the results. Compared to baseline Pennsylvania data from 2009, the rate of HAIs has decreased 3.0 percent overall with more significant improvements in specific areas. Using conservative estimates, this translates to an estimated minimum savings of \$150 million in direct health care costs.

PADOH uses three specific categories of HAIs for benchmarking. These are: catheter-associated urinary tract infections (CAUTIs), central line-associated bloodstream infections (CLABSI) and selected surgical site infections (SSIs). The Centers for Disease Control and Prevention (CDC) implemented several case definition changes between 2014 and 2015 that limit the validity of year-to-year comparisons. Due to these changes, 2015 CLABSI and bloodstream (BSI) rates are substantially greater than 2014 rates, while the secondary BSI and urinary tract infection (UTI) rates are significantly less than 2014 rates. Nonetheless, the case definition changes, if uniformly implemented, should not affect the interpretation of the standardized infection ratio (SIR) for benchmarking purposes.

The device utilization ratio (DUR) is an important and robust measure of patient safety and is unaffected by the aforementioned case definition changes. These metrics indicate how many patients are exposed to care that might ultimately result in a CAUTI or CLABSI. Despite increasingly complex medical care, Pennsylvania hospitals have steadily reduced their use of central lines and urinary catheters. The statewide urinary catheter and central line DURs decreased 21.8 and 7.13 percent, respectively, since 2009.

Similarly, SSI surveillance case definitions and statewide benchmarking changed in 2012 and 2013. This limits the usefulness of year-to-year comparisons; however; the steady and robust SSI decreases reported for certain procedure types are impressive and likely reflect real risk reduction. Since 2009, the HAI rate after a hip prosthesis (HPRO), abdominal hysterectomy (HYST), knee prosthesis (KPRO) or cardiac surgery (CARD) decreased 10.4, 20.4, 36.3, 46.6 percent respectively.

Antibiotic resistant organisms are a serious threat to patient safety and health care. The proportion of HAIs caused by methicillin-resistant *Staphylococcus aureus* (MRSA) has decreased substantially. In 2009, hospitals isolated MRSA in 8.17 percent of HAIs; in 2015, hospitals isolated MRSA in 5.33 percent of HAIs.

Health care worker influenza vaccination prevents absenteeism (30 percent reduction in some studies) and prevents transmission to patients and co-workers. During the 2015–2016 influenza season, 152 (60 percent) facilities reported an employee vaccination rate of 90 percent or better, a Healthy People 2020 goal. This is a 245 percent increase since the 2011-2012 influenza season.

The observed reduction in HAIs is likely the result of ongoing efforts undertaken by infection preventionists, health care personnel (HCPs) and systems, professional societies, and governmental agencies to control and prevent the occurrence of HAIs. The impact of ongoing efforts and new initiatives, guided by the best-available scientific evidence, should improve the health status and outcomes of patients cared for in Pennsylvania hospitals — the primary motivation for HAI prevention and control — as well as reduce health care expenditures.

**Background** All hospitals in Pennsylvania are required to report any HAI that occurs in an inpatient location. These infections are reported by the hospitals to CDC's National Healthcare Safety Network (NHSN), which is now the primary data collection tool used for HAI reporting by more than 5,000 hospitals across the country. The information submitted to NHSN from Pennsylvania hospitals is provided to PADOH in order to be compiled, analyzed and published on an annual basis.

As in previous reports, the 2015 report contains a summary of the overall and hospital-specific number and type of HAIs. This is followed by separate sections on each of the three HAI categories that PADOH uses for benchmarking hospital performance. Hospital comparisons in these sections are done using the same risk-adjusted standardized

infection ratio (SIR) approach used in previous Pennsylvania reports. The SIR is a value based on the ratio of infections **reported** by each hospital to NHSN (referred to as observed infections) to the number of infections **predicted** to occur at that hospital (referred to as predicted infections). The number of predicted infections is a calculated value that PADOH assigns to the hospital based on the overall statewide rate for each type of infection.

Universal influenza vaccination is the single most important measure to prevent transmission of influenza, and it is an important indicator of a hospital's commitment to patient safety. Health care provider (HCP) influenza vaccination of 90 percent or better is a Healthy People 2020 goal. The 2011 report was the first report in which PADOH reported statewide HCP influenza vaccination rates. This 2015 report includes hospital-specific HCP influenza vaccination rates during the 2015–2016 influenza season and recognizes those facilities that have already achieved the Healthy People 2020 goal.

**All Healthcare-Associated Infections (HAIs)** In 2015, there were 251 hospitals in Pennsylvania that submitted data to NHSN and were in continuous operation over the 12-month time period. Cumulatively, these hospitals reported a total of 23,623 HAIs occurring over 9,774,027 patient days of hospital care. Patient days are the number of hospitalizations multiplied by the length of stay of each hospitalization (i.e., one patient hospitalized for five days equals five patient days). This results in an overall statewide rate of 2.42 HAIs per 1,000 patient days. This is a 4.4 percent increase from the HAI rate in 2014 and is likely a result of case definition changes implemented by CDC between 2014 and 2015; nonetheless, the 2015 rate is 3.0 percent less than the 2009 rate, which is considered the baseline year of measurement for Act 52. This represents 9,971 fewer HAIs than would have occurred if the 2009 HAI rate had persisted into 2015. In this report, as in past reports, the three most commonly reported categories of HAIs are gastrointestinal infections (GI; 28.5 percent), SSIs (26.0 percent) and urinary tract infections (UTI; 19.0 percent).

**Catheter-Associated Urinary Tract Infections (CAUTIs)** Among the 251 hospitals, there were 228 (90.1 percent) that reported using urinary catheters and 165 (72.4 percent of those using urinary catheters) that reported at least one CAUTI. There were a total of 1,797 CAUTIs reported in 2015 among more than 1.4 million days of urinary catheter use, for a rate of 1.2 CAUTIs per 1,000 urinary catheter days. Due to case definition changes, infection rates should be compared to previous years with great care. The 2015 rate likely overstates the true risk reduction achieved by Pennsylvania hospitals. However, the definition of the device utilization rate has not changed over this period of time. The urinary catheter DUR has steadily decreased 21.8 percent since 2009. While device use is sometimes necessary and unavoidable, in general, less device use translates to fewer patients at risk for CAUTIs.

**Central Line-Associated Bloodstream Infections (CLABSIs)** Among the 251 hospitals, there were 217 (86.5 percent) that used central lines (catheters inserted into the large arteries near the heart) and 146 (67.3 percent of those using central lines) that reported at least one CLABSI. There were a total of 1,703 CLABSIs reported in 2015 among more than 1,539,281 million days of central line use, giving an overall rate of 1.1 CLABSIs per 1,000 central line days. This is 51.4 percent more than the rate in 2014. This very large rate increase is very likely a result in case definition changes implemented by CDC between 2014 and 2015 reporting years. Despite these changes, the 2015 CLABSI rate is still 10.3 percent less than the 2009 baseline rate. Like the CAUTI DUR, the CLABSI DUR provides a robust indicator of patient safety. The 2015 CLABSI DUR is 7.1 percent less than 2009 CLABSI DUR.

**Surgical Site Infections (SSIs)** A number of changes in SSI surveillance occurred in 2012 and 2013 as a result of changes to NHSN case definitions and CMS reporting requirements. These changes make year-to-year comparisons difficult. Colon surgeries were added in 2012 as a seventh benchmarked procedure. In addition, NHSN definitions for implant-associated surgical procedures currently require a three-month follow-up period to detect an SSI. It should be noted that this change in the NHSN case definition was implemented in 2013; prior to that, there was a 12-month follow-up period. The number of observed infections within a three-month follow-up period is likely to be modestly lower than with a 12-month follow-up period. It is also important to note that this data only reflects inpatient procedures and does not include procedures performed at ambulatory surgery centers or on an outpatient basis.

In 2015, at least one of the seven benchmarked procedures was performed in 169 Pennsylvania hospitals. For all seven procedures combined, a total of 115,975 procedures were performed in 2015. Knee prosthesis surgeries constitute

35.5 percent of all benchmarked surgeries. For all seven procedures combined, a total of 1,828 SSIs were identified in 2015. This produced overall rates of 1.6 SSIs per 100 procedures (unadjusted crude rate). These rates are higher than rates reported prior to 2012 because colon surgeries, now included in aggregate rates, account for 13.9 percent of all procedures and result in a disproportionate number of infections (i.e., 5.3 per 100 procedures in 2015). Nonetheless, the HYST SSI rate in 2015 is lower than any other year since reporting started in 2009. In addition, the 2015 KPRO and HPRO infection rate is 36.3 and 10.4 percent less than in 2009.

## 2 Introduction

HAI is the term used for an infection that occurs in a patient as a direct consequence of the health care interventions being delivered to them. HAIs are one of the major types of adverse events that can occur in the health care environment and are a considerable patient safety concern. HAIs represent a diverse group of complications, ranging from infections that occur in a surgical wound to pneumonia among patients on ventilators. They vary based on the reason that the patient is receiving care, the type of interventions being administered, the portion of the health care system being used by the patient, and the patient's underlying health status and circumstances. HAIs also vary substantially in terms of their impact on the patient, the outcome and their costs. They can be relatively minor and easily treatable (such as a minor skin infection in an outpatient) or they can result in significant patient deterioration, longer hospital stays and even death. Taken as a group, HAIs are considered among the leading causes of death in the United States and have been estimated to cost the health care system tens of billions of dollars annually.

These factors have resulted in a growing awareness of the importance of HAIs and have helped to establish patient safety as a core pillar of the health care system. Although HAIs are an important factor throughout the health care continuum, nowhere are they more impactful than in the hospital setting, where the sickest patients are usually treated.

As recently as the 1990s, HAIs were considered an inevitable consequence of health care delivery. But this view has shifted dramatically as HAIs have come to be recognized as preventable. This had led to a paradigm shift throughout the health care system that the elimination of HAIs as a public health and patient safety concern is a possibility and the ultimate goal. In a 2010 article co-authored by CDC and a consortium of patient safety organizations, four major pillars crucial to meeting the goal of elimination of HAIs were identified (Cardo *et al.*, 2010). They are:

1. Comprehensive, systematic and continuous adherence to evidence-based prevention practices;
2. Alignment of incentives to promote the adoption of prevention practices;
3. Conducting research to identify strategies to reduce HAIs where knowledge gaps remain; and
4. Collecting, analyzing and disseminating data for action.

Pennsylvania is considered a national leader in all of these areas. Researchers in the commonwealth have conducted some of the seminal studies used to develop the knowledge base for HAI prevention. Practitioners have demonstrated the impact of systematic implementation of HAI prevention strategies. Pennsylvania was one of the first states to require that all hospitals publicly disclose their HAI data.

The current report focuses on the fourth pillar of the HAI elimination blueprint published in 2010. Legislation known as Act 52 was passed and enacted in 2007 that contains the most comprehensive reporting requirements of any state. The act requires PADOH to collect information on all inpatient HAIs, summarize the findings and publicly report the results.

Since Act 52 requirements took effect in February 2008, PADOH has published a comprehensive report on the patterns of HAIs in Pennsylvania. The current report is the eighth in this series. It includes data on the overall patterns of HAIs in Pennsylvania acute care inpatient institutions and focuses on the three types of HAIs that are used to measure the progress in HAI reductions. These HAI types are known as benchmark HAIs. They were selected by PADOH in collaboration with a statewide HAI Advisory Committee established by Act 52 based on the volume of infections and their human and economic toll and preventability. They are CAUTIs, CLABSI and seven different types of SSIs. These HAI types were also selected to allow some type of measure to be established across the range of inpatient facilities present in a large, diverse state like Pennsylvania. Even the smallest hospitals are likely to use urinary catheters and to perform at least one of the seven surgical procedures.

With the growing focus on patient safety, the demand for measures of progress in reducing HAIs and in demonstrating a culture of patient safety is also growing. In addition to measuring actual trends in HAIs, there is growing interest in assessing process measures of patient safety. Therefore, PADOH started publishing influenza vaccination rates for health care workers in the 2011 report. This section examines vaccination coverage of the health care workforce

against influenza. Influenza is recognized as a major cause of illness and death, can be transmitted in health care settings, and is preventable through vaccination. Major health care organizations, societies, and federal and state governments have all promoted influenza vaccination of health care workers to control influenza and to keep the workforce healthy. The U.S. Department of Health and Human Services has established a Healthy People 2020 goal of 90 percent of health care workers to be vaccinated against influenza annually.

This is the fifth PADOH HAI annual report to contain health care worker influenza vaccination data and the fourth annual report to include facility-specific rates. Submission of data on health care worker vaccination is not a mandated requirement of Act 52; however, in January 2013, CMS implemented pay-for-reporting requirements. For hospitals to receive full reimbursement from CMS within the inpatient prospective payment system (IPPS), hospitals are required to submit data to NHSN system that is currently used by Pennsylvania to report HAIs. In the 2011 report, PADOH published aggregated health care worker vaccination rates and recognized the accomplishments of those facilities that achieved employee vaccination rates of 90 percent or better, but PADOH did not publish facility-specific rates. Since then, PADOH has included facility-specific rates in its annual reports.

As in previous reports, the information in 2015 is divided into several sections. First, composite information is provided for the entire state. This is followed by hospital-specific data on the overall numbers of HAIs in each reporting category in NHSN. Separate sections then focus on CAUTIs, CLABSIIs and SSIs, followed by the section on health care worker flu vaccination.

It is important to note that PADOH works collaboratively with a variety of stakeholder organizations to promote health care quality and reduce the incidence of healthcare-associated infections. In addition, two governmental partners, the Pennsylvania Patient Safety Authority (PSA) and the Pennsylvania Health Care Cost Containment Council (PHC4), have specific roles under Act 52 and work closely with PADOH on HAI prevention and control. Readers of the annual report are encouraged to examine companion reports published by PSA and PHC4. The PSA annual report for 2015 describes PSA HAI-related activities and can be found at <http://patientsafetyauthority.org>. The PHC4 report titled, "The Impact of Healthcare-Associated Infections in Pennsylvania, 2010," examines costs, mortality, readmissions and underlying health conditions associated with HAIs. It can be found at <http://www.phc4.org>.

### **3 Data and Methods**

The data, analytic approaches and methods used in this report are similar to those used in previous reports. They are described in much greater detail in the 2009 report, which is available on the Pennsylvania Department of Health website at the following address: [http://www.health.pa.gov/facilities/Consumers/Healthcare%20Associated%20Infection%20\(HAI\)/Pages/default.aspx](http://www.health.pa.gov/facilities/Consumers/Healthcare%20Associated%20Infection%20(HAI)/Pages/default.aspx).

All hospitals are required to report all HAIs associated with any inpatient location using the Patient Safety Module of CDCs National Healthcare Safety Network. These infection types are:

- Bone and joint infections (BJ);
- Blood stream infections (BSI) with or without a central line (BSI associated with a central line are known as central line associated bloodstream infections [CLABSI]);
- Central nervous system infections (CNS);
- Cardiovascular system infections (CVS);
- Eye, ear, nose and throat infections (EENT);
- Gastrointestinal infections (GI);
- Lower respiratory tract infections (LRI);
- Pneumonia (PNEU) whether ventilator or non-ventilator associated;
- Reproductive tract infections (REPR);
- Skin and soft tissue infections (SST);
- Surgical site infections (SSI);
- Systemic infections (SYS); and
- Urinary tract infections (UTI) with or without a catheter (UTI associated with a urinary catheter are known as catheter-associated urinary tract infections [CAUTI]).

NHSN uses standardized definitions for each of these infection types, including methods for their detection, how they are to be identified, and the time frames for the infection to occur upon and after hospitalization. The NHSN definitions can be found in the NHSN Patient Safety Manual at <http://www.cdc.gov/nhsn>. Infection preventionists and data reporters under Act 52 are required to use the standardized NHSN criteria and methods to determine whether an identified infection should be reported as an HAI.

Hospitals also collect certain denominator information to enable the calculation of HAI rates. This information includes:

- Patient days: the total number of patients in the hospital per day over the entire calendar year (total hospitalizations multiplied by the duration of each hospitalization);
- Urinary catheter days: the total number of hospitalized patients with a urinary catheter in place per day over the entire calendar year (total number of patients with a urinary catheter in place multiplied by the number of days a catheter was used for each patient); and
- Central line days: the total number of hospitalized patients with a central line in place per day over the entire calendar year (total number of patients with at least one central line in place multiplied by the number of days

a central line was in place for each patient).

**It is important to note that several NHSN case-definitions changed between 2014 and 2015, resulting in significant swings in several HAI types.** These changes affected the classification of bloodstream infections (BSI; including CLABSI) and secondary BSI. These changes also affected the classification of urinary tract infections (UTI). **As a result, year-to-year comparisons of 2014 and 2015 data for all-cause HAIs, BSIs (inclusive of CLABSI and secondary BSIs) and UTIs (inclusive of CAUTIs) are extremely problematic and may not be valid.**

For the seven benchmarked surgical procedures, hospitals collect and submit certain standardized information on all patients who had the procedure performed during the period of interest, not just those in whom an HAI subsequently developed. This includes risk index information for all patients undergoing one of the benchmarked procedures, allowing risk index-specific HAI rates for each procedure category.

The overall rate of HAIs by hospital (Table 4.2.4) is calculated as infections per 1,000 patient days. This is a standard method of reporting HAIs. All of the reported rates are unadjusted for factors that might be related to differences in HAIs between or within a hospital, such as the type and intensity of care, size of the facility or differences in patient populations.

Elsewhere in the report, CLABSI and CAUTI rates are reported per 1,000 device days (either catheter days or central line days), since these are the more appropriate denominators. Similarly, for benchmarked SSIs, the rates are reported as infections per 100 procedures.

Hospitals also complete accessory reports that indicate the ward types present in their facility, the number of infection preventionists and hospital characteristics (including number of beds). This information is summarized in Table 4.1.1.

NHSN contains certain basic error checks that help to ensure that the information reported into the system is valid. PADOH also reviews the information submitted by each Pennsylvania hospital on a quarterly basis to spot unusual patterns or information that might suggest reporting errors or incomplete reporting. Each hospital receives a data integrity verification (DIV) report every 90 days that includes a list of any questionable reports submitted in the preceding quarter. The hospital is then given 30 days to review and correct the information before the data are considered locked down for analytical purposes. In 2011 and 2012, with funding from the American Recovery and Reinvestment Act, PADOH conducted limited audits of selected hospitals to further determine the accuracy of the information reported in NHSN. The auditing process focused on the benchmarking categories of CAUTIs, CLABSI and SSIs in order to identify inaccurately reported infections and unreported infections.

Act 52 requires PADOH to: (1) assess overall trends in HAIs in Pennsylvania, (2) compare the rates of HAIs in Pennsylvania to the rates elsewhere in the country, and (3) compare the occurrence of HAIs between hospitals and over time in each hospital. To assess overall HAI trends in Pennsylvania, PADOH produces summary statistics on the patterns of HAIs by category, the overall rates of HAIs and the rates by category. Information is also provided on the pathogens causing HAIs, with an emphasis on infections caused by methicillin-resistant *Staphylococcus aureus* (MRSA), which was a special focus of Act 52.

To compare Pennsylvania's rates and patterns of HAIs to the rest of the country, this report uses information contained in the NHSN progress report. NHSN now collects data from more than 5,000 hospitals across the United States and produces the definitive dataset on HAIs. The latest CDC progress report from NHSN can be found here: <http://www.cdc.gov/hai/progress-report>.

To compare differences between hospitals, the recommended approach is the use of a standardized infection ratio, or SIR. The SIR is a comparison between the reported occurrence (the **observed** number of infections) of a specific HAI (e.g., CAUTI or CLABSI) in a hospital to the number that would be predicted to occur in that hospital if the hospital's rate was identical to the statewide HAI rate for that infection type. If a hospital reported 10 CAUTIs during 2015 and, based on the overall statewide rate of CAUTIs per 1,000 catheter days, we would have predicted only five CAUTIs should occur in that hospital, the SIR would be 10/5 or 2.00. If another hospital reported five CAUTIs and, based on statewide rates, we would have predicted the hospital would have 10 CAUTIs, the SIR would be 5/10 or 0.50. An SIR of 1.00 means the hospital reported exactly the same number of infections as predicted

based on statewide rates (i.e., the hospital's rate was exactly the same as the statewide rate). A SIR >1.00 means the hospital reported more infections than predicted, and an SIR <1.00 means the hospital reported fewer infections than predicted. Facilities with no patient or device days for a given infection type and year are included in tables with “.” to denote the absence of data for that year.

Differences between hospitals (such as intensity of care or patient populations) may explain why they have differences in their HAI rates. Some hospitals care for sicker patients, and these patients are at higher risk for an HAI with all other factors being equal. To account for such differences, an adjustment is made to the predicted number of infections (the predicted number is adjusted upward for hospitals that provide more complex care and downward for hospitals that provide less complex care). It is difficult to precisely measure complexity of care. Factors that were examined for this purpose for CAUTIs and CLABSIs include device utilization ratio (how often a catheter or central line is used in each hospital, calculated as the number of catheter or central line days divided by the number of patient days; DUR), the bed size of the hospital, the geographic location of the hospital (urban or rural), and whether the hospital is affiliated with a medical school. These factors have been shown in medical literature to influence the likelihood of an HAI as a surrogate for patient population differences or intensity of care. The final risk adjustment model for CAUTIs and CLABSIs incorporates the DUR and medical school affiliation, similar to previous reports. For SSIs, such adjustments are not needed, as information is collected on all patients who underwent a procedure, whether or not an infection subsequently occurred. Adjustment factors for predicting the number of infections used for SSIs include the American Society of Anesthesiology (ASA) score (the patient's level of health), duration of the surgical procedure, and whether the operation site was clean or contaminated. Together, these comprise the risk index.

Before 2013, the CDC definition of a SSI included a 12-month follow-up period. Since 2013, the follow-up period was reduced to 90 days. As a result, this report includes SSIs that occurred after procedures performed in 2012 (12-month follow-up) and 2013 (90-day follow-up). Any comparison of 2013 SSI data to previous years will be influenced by the case definition change and any year-to-year comparisons should be interpreted cautiously. In addition, colon surgeries were added a seventh benchmarked procedure in 2012.

After the SIR is calculated, a determination is made regarding whether any differences seen between hospitals are statistically meaningful. For a small hospital that performs few operative procedures or uses very few catheters or central lines, the level of confidence in the reliability of the calculated rates is lower than for a larger hospital. This is reflected in a calculation known as the confidence interval or CI, for which a lower limit and an upper limit are calculated and displayed. The true SIR for the hospital is found somewhere in between the lower value and the upper value of the confidence interval. In general, the smaller the facility, the wider the confidence interval, meaning our confidence in the calculated rate is low. Larger facilities tend to have narrower confidence intervals, meaning there was more information available to calculate the rates. If the two values in the confidence interval are both <1.00, it means the observed number of infections in that hospital is significantly lower than predicted. If both values in the confidence interval are >1.00, it means there are significantly more infections than predicted. If the confidence interval includes the value of 1.00, it means the observed number of infections is not statistically different than predicted based on statewide rates. Hospitals with a significantly lower number of observed infections are depicted in green in the graphs included in the report; hospitals with a significantly higher number of observed infections are depicted in red in the graphs. Hospitals that are no different than predicted are depicted in gray in the graphs.

For the section on health care worker influenza vaccination, hospitals were asked to voluntarily submit information on the number of health care workers in their facility and the number of these workers that were documented to have received influenza vaccine (whether or not the vaccine was administered at the hospital) for the 2015–2016 flu season. The methods for counting vaccination are based on those developed by the National Quality Forum (NQF), which uses three separate categories (hospital employees, licensed independent practitioners, and adult volunteers or students) and counts only those present in the hospital for at least 30 days during the flu season. For this report, hospitals submitted healthcare worker vaccination data directly to NHSN. That is the source of vaccination data in this report for the 2015–2016 influenza season.

Manuscript preparation and all analyses were performed using R (version 3.3.1; R Core Team, 2015) and RStudio (version 0.99.903; RStudio Team, 2015).

## 4 Results

### 4.1 Hospital Characteristics

In 2015, a total of 251 Pennsylvania hospitals reported data on the occurrence of healthcare-associated infections to NHSN for the entire calendar year. The characteristics of these hospitals are found in Table 4.1.1.

Table 4.1.1: Characteristics of hospitals (n = 251) reporting healthcare-associated infections — Pennsylvania, 2015

		N	%
Facility type			
	Acute care hospital	161	64.14
	Critical access hospital	14	5.58
	Children's hospital	6	2.39
	Long term acute care	23	9.16
	Psychiatric hospital	27	10.76
	Rehab hospital	20	7.97
Medical school affiliation	Affiliation	87	34.66
	No affiliation	164	65.34
Number of infection preventionists	0	1	0.40
	< 1	18	7.17
	1 to 2	159	63.35
	2 to 3	43	17.13
	3 to 4	12	4.78
	>= 4	18	7.17
Hospital bed size	<=200	175	69.72
	201-500	60	23.90
	>500	16	6.37

### 4.2 Overall Patterns of Healthcare-Associated Infections (HAIs)

Among the 251 reporting hospitals, there were a total of 23,623 healthcare-associated infections reported (Table 4.2.1). These HAIs occurred over a total of 9,774,027 patient days of care in Pennsylvania hospitals. The number of reported HAIs in 2015 is 4.75 percent more than in 2014, and the number of patient days in 2015 is 0.316 percent more than in 2014. The overall rate of HAIs in 2015 is 2.42 HAIs per 1,000 patient days, which is 4.42 percent more than the rate of 2.31 per 1,000 patient days in 2014; however, the rate of HAIs reported in 2015 is 2.98 percent less than the rate of 2.5 HAIs per 1,000 patient days since 2009 (the baseline year for Pennsylvania data). These declines translate to **9,971 fewer** healthcare-associated infections having occurred in Pennsylvania since 2009.

Table 4.2.1: Healthcare-Associated Infections — Pennsylvania, 2009–2015

Year	Number of HAIs	Number of Patient Days	Rate per 1,000 Patient Days	Percent Decline (prior year)	Percent Decline (since 2009)
2015	23,623	9,774,027	2.42	4.42	-2.98
2014	22,552	9,743,208	2.31	-5.45	-7.09
2013	24,103	9,845,909	2.45	8.42	-1.73
2012	22,654	10,033,090	2.26	1.52	-9.36
2011	22,713	10,212,208	2.22	-3.04	-10.72
2010	23,601	10,289,079	2.29	-7.92	-7.92
2009	25,914	10,402,161	2.49	.	.

<sup>a</sup> In the 2009–2011 reports, manual changes were made to 2009 patient days based on communication with facility infection preventionists. In this report, we have chosen to report values in NHSN as entered by the facility. Therefore, 2009 patient day data and any subsequent reanalysis of 2009 data may yield different results.

Among, the 23,623 HAIs that occurred in 2015, the most common types are found in Table 4.2.2. Gastrointestinal (28.5 percent), surgical site (26.0 percent) and urinary tract (19.0 percent) infections continue to be the most frequently reported HAIs.

Table 4.2.2: Healthcare-Associated Infections—Pennsylvania, 2010–2015

#### 4.2.1 Methicillin-Resistant *Staphylococcus aureus* (MRSA)

Methicillin-resistant *Staphylococcus aureus* (MRSA) continues to be a serious concern in the health care setting. Act 52 instituted specific requirements related to MRSA, including screening of high-risk patients on admission. The department's annual HAI reports have included information on the incidence of MRSA and progress in reducing the burden of this infection in Pennsylvania. Table 4.2.3 shows the total number of HAIs due to MRSA for each type of HAI in 2013 through 2015. The absolute number of reported HAIs caused by MRSA has steadily declined 34.8 percent, from 2,117 infections in 2009 to 1,258 infections in 2015. The proportion of HAIs attributable to MRSA has also decreased substantially. In 2009, hospitals isolated MRSA in 8.17 percent of HAIs; in 2015, hospitals isolated MRSA in 5.33 percent of HAIs.

Table 4.2.3: Methicillin resistant *Staphlococcus aureus* Healthcare-Associated Infections — Pennsylvania, 2013–2015

#### 4.2.2 HAIs and Unadjusted (Crude) Infection Rates by Facility

Table 4.2.4 presents the overall patterns of HAIs by hospital. Included is the organizational identifying number used by the hospital in NHSN. Of note, some hospitals with separate campuses report HAI data to NHSN separately for each campus and use different NHSN numbers. Other hospitals report such data in merged fashion and use only a single, unified NHSN number.

The hospital name, the number of patient days the hospital reported, the total number of HAIs, the number of HAIs by category and the number of infections per patient days are also listed in 4.2.4. This information is followed by the crude rate of HAIs per 1,000 patient days. It is important to note that the crude rates are **not** risk-adjusted and therefore should not be used for hospital-to-hospital comparisons. However, unless there is a change in a hospital's status (such as a merger, closure of hospital units or expansion), or a change in the case definition as occurred between 2014 and 2015 for BSI and UTI and in 2012 and 2013 for SSI, then the crude rate can be used to illustrate trends over time (changes in annual rates).

## 4.3 Catheter-Associated Urinary Tract Infections (CAUTIs)

### 4.3.1 CAUTIs — Statewide Summary

In 2015, urinary tract infections constitute the second most commonly reported category of HAIs in Pennsylvania, with 4,478 (18.96 percent; see Table 4.2.2) occurrences. Almost half (1,797 or 40.13 percent) of the UTIs were associated with the use of urinary catheters, which are one of the more commonly used medical devices in hospital settings. In 2015, a total of 1,465,489 urinary catheter days (Table 4.3.1) were reported by 228 Pennsylvania hospitals (urinary catheter days ranged from a low of four for the year to a high of 62,216 among the 228 hospitals). The number of hospitals that reported using urinary catheters in 2015 represents 90.84 percent of the 251 hospitals that reported data through NHSN. The 23 with no reported use of urinary catheters are mostly psychiatric or drug and alcohol rehabilitation facilities and can be found in Table 4.3.6.

Table 4.3.1: Summary of Catheter-Associated Urinary Tract Infections — Pennsylvania, 2009–2015

Number of CAUTI	Urinary Catheter Days	Rate per 1,000 Catheter Days (95%CI)	Percent Change in Rate Prior Year (Since 2009)	Patient Days	Device Utilization Ratio (DUR)	Percent Change in DUR Prior Year (Since 2009)
2015	1,797	1.23 (1.17–1.28)	– 32.46 ( – 37.83)	9,774,027	0.15	– 2.67 ( – 21.83)
2014	2,725	1.82 (1.75–1.88)	– 4.52 ( – 7.95)	9,743,208	0.15	– 7.30 ( – 19.68)
2013	3,111	1.90 (1.84–1.97)	11.43 ( – 3.60)	9,845,909	0.17	– 0.87 ( – 13.35)
2012	2,870	1.71 (1.64–1.77)	10.22 ( – 13.49)	10,033,090	0.17	– 5.98 ( – 12.59)
2011	2,819	1.55 (1.49–1.61)	– 9.61 ( – 21.51)	10,212,208	0.18	– 3.17 ( – 7.03)
2010	3,245	1.71 (1.65–1.77)	– 13.16 ( – 13.16)	10,289,079	0.18	– 3.99 ( – 3.99)
2009	3,935	1.97 (1.91–2.03)	.	10,402,161	0.19	.

The number of urinary catheter days (1,995,114), divided by the total number of patient days (10,402,161) reported in 2015 produces a DUR of 0.1, meaning that a urinary catheter was used 15.0 percent of the time in Pennsylvania’s hospitalized patients (Table 4.3.1). As expected, urinary catheter use is highest in critical care units where the sickest patients are receiving care. Catheter use was highest in surgical intensive care units (65.3 percent of the time), in surgical trauma intensive care units (64.8 percent of the time) and in cardiothoracic critical care units (63.0 percent of the time).

Among the 228 hospitals that reported any use of urinary catheters, 165 (72.4 percent) of them reported at least one CAUTI while the other 63 (27.6 percent) reported no identified CAUTIs. Pennsylvania’s CAUTI rate for 2015 was 1.23 CAUTIs per 1,000 urinary catheter days (Table 4.3.1). This is a decrease of 32.46 percent compared to last year’s rate of 1.82 CAUTIs per 1,000 urinary catheter days. This dramatic decrease is likely due to the case definition changes implemented between 2014 and 2015. Overall, the rate reductions since 2009 translate to **3,157 fewer** CAUTIs than would have otherwise occurred if the 2009 rate persisted into 2015. This likely under estimates the true impact of prevention efforts because urinary catheter use (DUR) has also decreased a total of 21.83 percent since 2009 (Table 4.3.1). The observed, steady DUR reduction is not impacted by the aforementioned case definition change.

#### 4.3.2 CAUTIs — By Unit Type

The risk of a CAUTI varies substantially in the different areas of a hospital (Table 4.3.2). In 2015, CAUTI rates (per 1,000 catheter days) were highest in intensive care burn units (cc:Burn: 4.19), behavioral health wards (w:Behavior: 2.6), surgical intensive care units (cc:Surgery: 2.58). Among locations with at least 1,000 urinary catheter days, NICU (NICU: 0), labor and delivery and post-partum units (w:LD\_pp: 0.049) and pediatric medical/surgical units (w:Ped\_ms: 0.88) reported the lowest CAUTI rates per 1,000 urinary catheter days (Table 4.3.2).

Table 4.3.2: Catheter-Associated Urinary Tract Infections (CAUTI), Infection Rates per 1,000 Patient Days and Device Utilization Rates (DUR) by Location within Facility—Pennsylvania, 2009–2015

Number of CAUTI	Urinary Catheter Days	Rate per 1,000 Catheter Days	Patient Days	Device Utilization Ratio — DUR (Cath. Days / Pt. Days)

#### 4.3.3 CAUTIs — By Pathogen

In 2015, hospitals reported a total of 2,003 organisms (or isolates) from 1,797 CAUTIs (some patients had an infection with more than one organism). Consistent with previous years, three pathogens (i.e., *Escherichia coli*, *Pseudomonas aeruginosa*, *Klebsiella pneumoniae*) accounted for 59.96 percent of isolates cultured from patients with a CAUTI (Table 4.3.3). The 14 organisms listed in Table 4.3.3 account for 92.51 percent of isolates cultured from CAUTIs. The remaining isolates (7.49 percent) cultured from CAUTIs in 2015 are from 45 other pathogens, each individually accounting for less than 1 percent of the total results.

Table 4.3.3: Pathogens Isolated in Catheter-Associated Urinary Tract Infections — Pennsylvania, 2014–2015

Pathogen	2014		2015	
	Count	%	Count	%
<i>Escherichia coli</i>	797	26.06	658	32.85
<i>Pseudomonas aeruginosa</i>	324	10.60	304	15.18
<i>Klebsiella pneumoniae</i>	287	9.39	239	11.93

Other	888	29.04	150	7.49
All	3,058	100.00	2,003	100.00

#### 4.3.4 CAUTIs — By Facility

Table 4.3.7 lists alphabetically the 228 hospitals that reported using urinary catheters in 2015. Among these facilities, a total of 150 (65.8 percent) had a SIR that was  $< 1.00$ , meaning they reported fewer CAUTIs than predicted by PADOH based on the statewide rate of CAUTIs and adjusting for characteristics of each facility. For 63 (27.6 percent) of these hospitals, the SIR was 0.00, as they reported no CAUTIs in 2015. There were 78 (34.2 percent) that had an SIR that was  $> 1.00$ , meaning that they reported a greater number of CAUTIs than predicted by PADOH based on the statewide CAUTI rate.

To compare a facility's adjusted CAUTI rate (SIR), find the facility in Table 4.3.7 listed in alphabetical order and its corresponding number of predicted infections; the SIR figures (Figures 4.3.1–4.3.6) divide the list of hospitals into tiers based on their number of predicted infections. This is because hospitals with similar numbers of predicted infections are generally similar in size and other attributes. The categories used in the 2015 report are consistent with previous reports.

For many of the hospitals, the difference between the number of CAUTIs reported in NHSN and the number predicted by PADOH is not statistically meaningful. This occurs in situations in which the hospital's use of urinary catheters is low or when the difference between the observed number and predicted number is relatively small. As an example, 47 (20.6 percent) of facilities that reported using urinary catheters are predicted to have fewer than one CAUTI based on the characteristics of the facility and the number of urinary catheters used. Data from such hospitals is considered statistically unreliable, and the level of confidence in the reported results is low. In Figures 4.3.1–4.3.6, this statistical imprecision is visualized by large confidence interval bars around the estimated SIR (black point). A confidence interval bar that is shaded grey indicates that the facility's SIR is not statistically different from the statewide rate.

However, there were 26 (11.4 percent) facilities in which the reported number of CAUTIs was statistically better than predicted by PADOH. These hospitals are listed in Table 4.3.4 in alphabetical order, and their confidence interval bars are shaded green in Figures 4.3.1 – 4.3.6. There were also 20 (8.8 percent) facilities in which the reported number of CAUTIs was significantly worse than predicted by PADOH. These hospitals are listed in Table 4.3.5 in alphabetical order, and their confidence interval bars are shaded red in Figures 4.3.1 – 4.3.6.

Please note that unlike SIRs calculated by CDC, the SIRs in this report and previous PADOH reports are indexed relative to the performance of facilities with similar attributes for the **same** year. Therefore, a facility's crude CAUTI

rate (number of infections per 1,000 catheter days) may improve from year-to-year, but the improvement might not be reflected in the facility's SIR if the facility's improvement is consistent with improvements made statewide over the same period. SIRs should only be used to compare facility performance to other facilities in the state during the same reporting period. Furthermore, SIRs calculated by PADOH should not be compared to national SIRs or ratios reported from other states. For these reasons, crude rates should be used for trend analyses as reported in Tables 4.2.4 and 4.3.7.

## 4.4 Central Line-Associated Bloodstream Infections (CLABSIs)

### 4.4.1 CLABSIs — Statewide Summary

Central lines (also known as central venous catheters) are those catheters that are inserted into the large blood vessels of the body and usually end in proximity to the heart. They are generally used for the purposes of administering intravenous medications or to more closely monitor a patient's cardiac function and stability. If microorganisms are inadvertently introduced through the central line or the line becomes infected through improper care, a bloodstream infection is the usual result. Such infections, known as central line-associated bloodstream infections, are particularly severe because the infecting pathogen travels throughout the body and causes sepsis and because patients with central lines usually have significant underlying health problems that place them at increased risk for poor outcomes from complications. CLABSIs are associated with prolonged hospital stays, high additional health care costs and high mortality. Therefore CLABSIs are often the focus for infection prevention and control measures, and they are the single category of HAIs most often monitored by hospitals and health departments.

In the present report, as in previous ones, the facility-specific CLABSI tables are separated into several different locations in the hospital, including neonatal intensive care units (NICUs) and specialty care areas (SCAs), following CDC convention. All other critical care and ward locations are combined into a category known as ICU/other — a category that includes the bulk of central line days and data. CLABSI data are also reported separately for long-term acute care facilities (LTACs), since studies have shown CLABSI rates can be different in LTAC settings.

Since 2009, the incidence of CLABSIs in Pennsylvania has declined 10.28 percent (Table 4.4.2, Figure 4.4.1); however, the 2015 rate is 51.5 percent higher than 2014. This dramatic increase in the CLABSI rate is likely due to implementation of new CDC case definitions between 2014 and 2015. These case definition changes affected the way primary and secondary BSI are categorized. In 2015, hospitals reported fewer secondary BSI and more BSI, including CLABSIs. Comparison of 2014 and 2015 crude BSI or CLABSI rates is not recommended. Also, as previously noted, PADOH calculates its own standardized infection ratios, using statewide data from the year of analysis as a baseline. Therefore, year-to-year changes in the SIR should also be interpreted cautiously. The definition of the central-line device utilization rate has not changed, and year-to-year comparisons are still valid.

In 2015, a total of 217 (86.45 percent) of the 251 Pennsylvania hospitals reported use of central lines in any of their hospital locations. The 34 hospitals not reporting any use of central lines are mostly psychiatric, drug and alcohol rehabilitation centers or specialty hospitals. These facilities are listed in Table 4.4.7. Among the hospitals using central lines, 144 used them in the ICU and/or other ward locations and 23 institutions were long-term care facilities. The remaining facilities reported central line days from multiple ward types as shown in Table 4.4.1.

Table 4.4.1: Number of Facilities Reporting Central Line Days by Reporting Location — Pennsylvania, 2015

	Number of Facilities
ICUs and other wards	144
ICUs, other wards, and specialty care areas	8
ICUs, other wards, specialty care areas and NICUs	15
ICUs, other wards and NICUs	27
Long-term acute care facilities	23
All	217

Among the 217 hospitals that used central lines in 2015, a total of 146 (67.3 percent) reported at least one CLABSI. During 2015, there were a total of 1,703 CLABSIs reported (Table 4.4.2). Among the 1,703 CLABSIs, 93 (5.5 percent) occurred in the NICU, 327 (19.2 percent) occurred in SCAs, 156 (9.2 percent) occurred in LTACs, 497 (29.2 percent) occurred in ward locations, and 630 (37.0 percent) occurred in critical care units (other than the NICU; Figure 4.4.1).

Figure 4.4.1: Central Line-Associated Bloodstream Infections (CLABSI) by Unit Type — Pennsylvania, 2015

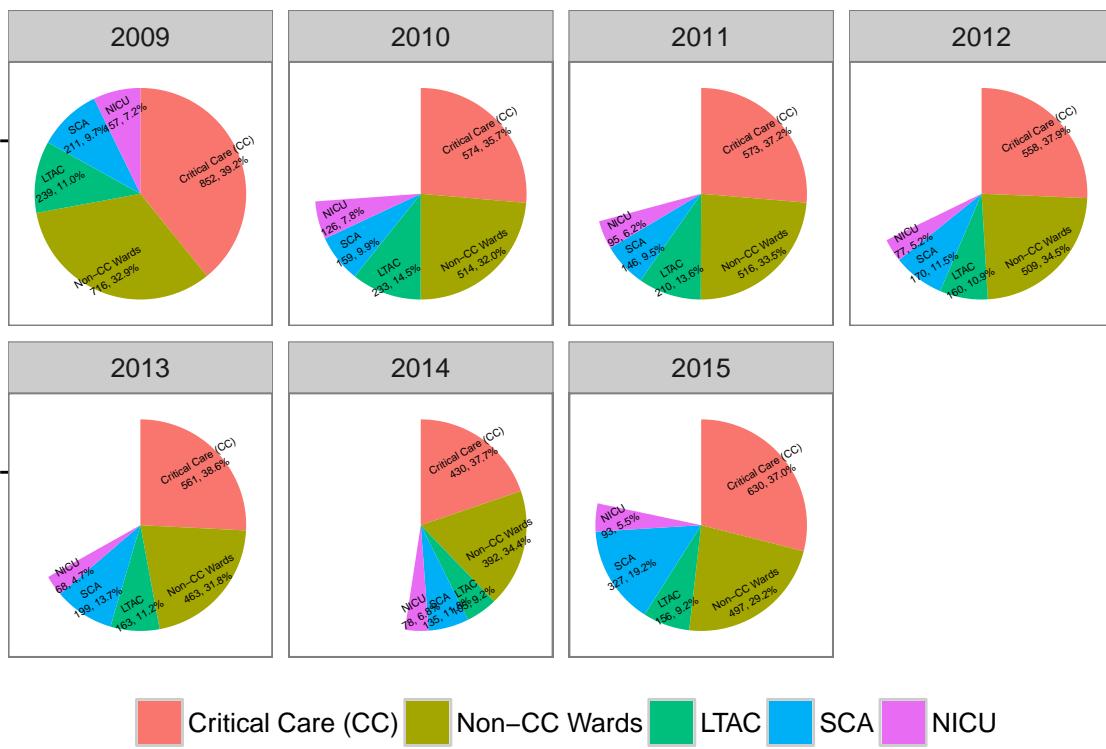

Table 4.4.2: Summary of Central Line-Associated Bloodstream Infections (CLABSI) — Pennsylvania, 2009–2015

Number of CLABSI	Central Line Days	Rate per 1,000 Central Line Days (95%CI)		Percent Change in Rate Prior Year (Since 2009)	Patient Days	Device Utilization Ratio (DUR)	Percent Change in DUR Prior Year (Since 2009)
2015	1,703	1,539,281	1.11 (1.05–1.16)	51.48 (–10.28)	9,774,027	0.16	–1.69 (–7.13)
2014	1,140	1,560,837	0.73 (0.69–0.77)	–17.83 (–40.77)	9,743,208	0.16	–3.58 (–5.53)
2013	1,454	1,635,871	0.89 (0.84–0.94)	0.22 (–27.92)	9,845,909	0.17	0.30 (–2.02)
2012	1,474	1,662,062	0.89 (0.84–0.93)	–0.39 (–28.08)	10,033,090	0.17	–2.20 (–2.31)
2011	1,540	1,729,770	0.89 (0.85–0.94)	–3.93 (–27.80)	10,212,208	0.17	0.57 (–0.11)
2010	1,606	1,732,994	0.93 (0.88–0.97)	–24.84 (–24.84)	10,289,079	0.17	–0.67 (–0.67)
2009	2,175	1,763,902	1.23 (1.18–1.29)	.	10,402,161	0.17	.

These CLABSIs occurred over a total of 1,539,281 central line days. The range of central line days reported by hospitals in 2015 ranged from 6 central line days to a high of 93,736 central line days.

The absolute number of CLABSIs reported in 2015 was 49.39 percent higher than in 2014, and the number of central line days reported in 2015 was 1.38 percent lower than in 2014. The device utilization ratio decreased 1.69 percent between 2014 and 2015. The CLABSI rate for 2015 was 1.11 CLABSIs per 1,000 central line days; this is a increase of 51.48 percent from 2014 to 2015 and a 10.28 percent decrease from 2009 to 2015. This translates to 3,242 fewer CLABSIs in Pennsylvania than would have occurred if the 2009 CLABSI rate had persisted into 2015.

#### 4.4.2 CLABSI — By Unit Type

Table 4.4.3: Central Line-Associated Bloodstream Infections (CLABSI), Infection Rates per 1,000 Patient Days and Device Utilization Rates (DUR) by Location within Facility—Pennsylvania, 2009–2015

			Rate per 1,000 Central Line Days	Patient Days	Device Utilization Ratio — DUR (Line Days / Pt. Days)
Number of CLABSI	Central Line Days				
Neonatal Intensive Care Unit (NICU)

Several different types of central lines are used in medical care. These include central lines that are temporarily inserted, those that are permanently inserted and central lines that are inserted through the umbilicus for use in infants. Before 2011, these line types were reported separately. However, changes were made to NHSN in 2011, and now the line type is only reported in specialty care areas (Figure 4.4.2.) Notably, the SCA CLABSI rate for temporary central lines nearly tripled between 2014 and 2015 but not for permanent central lines.

Figure 4.4.2: Central Line-Associated Bloodstream Infections (CLABSI) Reported by Specialty Care Areas (SCA) Among Patients with Permanent and Temporary Central Lines — Pennsylvania, 2009–2015

#### 4.4.3 CLABSIs — By Pathogen

In 2015, hospitals reported a total of 1,928 isolates from 1,703 CLABSIs (some patients had an infection with more than one organism). Consistent with previous years, three pathogens (i.e., *Staphylococcus aureus*, *Klebsiella pneumoniae*, *Enterococcus faecalis*) accounted for 31.28 percent of isolates cultured from patients with a CLABSI (Table 4.4.4). The 16 organisms listed in Table 4.4.4 account for 80.08 percent of isolates cultured from CLABSIs. The remaining isolates (19.92 percent) cultured from CLABSIs in 2015 are from 125 other pathogens, each individually accounting for less than 1 percent of the total results. The patterns seen in 2015 are not substantially different than those in 2014.

Table 4.4.4: Pathogens Isolated in Central Line-Associated Infections — Pennsylvania, 2014–2015

Pathogen	2014		2015	
	Count	%	Count	%
<i>Staphylococcus aureus</i>	209	15.99	270	14.00
<i>Klebsiella pneumoniae</i>	94	7.19	171	8.87
<i>Enterococcus faecalis</i>	115	8.80	162	8.40
<i>Escherichia coli</i>	88	6.73	149	7.73
<i>Enterococcus faecium</i>	73	5.59	130	6.74
<i>Candida albicans</i>	66	5.05	111	5.76

All	1,307	100.00	1,928	100.00

#### 4.4.4 CLABSIs — By Facility

Among the 194 hospitals that used central lines in intensive care or general ward units (the ICU-Other category), 134 (69.1 percent) had a standardized infection ratio (SIR) less than 1.00, meaning the hospital reported **fewer** CLABSIs than predicted based on statewide rates; 60 hospitals (30.9 percent) had a SIR greater than 1.00, meaning the hospital reported **more** CLABSIs than predicted.

For many of the hospitals, the difference between the observed number (number reported by the hospital) of infections and predicted number of infections was not statistically meaningful. This occurs either when the hospital has a small number of patients with central lines in place or when the difference between the observed and predicted number is small. In such circumstances, the reliability (as demonstrated by the wide confidence intervals in the tables and figures) is lower, and the "true" SIR may be either less than 1.00 or greater than 1.00. As one example of this problem, a total of 76 (39.2 percent) of the hospitals had a predicted number of CLABSIs in their ICUs and wards that was less than one. Rates from these hospitals often appear to change quite a bit from year to year because of the statistical imprecision inherent in calculating a rate with so few predicted infections. Findings for hospitals with such a low number of predicted infections are considered to be statistically unreliable, and the findings should be very cautiously interpreted and used.

Among the 194 hospitals in the ICU-other category, four hospitals (2.1 percent) had a reported number of CLABSIs that was significantly better than predicted. These hospitals are listed below in Table 4.4.5 in alphabetical order and

are designated in green in Figures 4.4.3 – 4.4.7. In contrast, eight hospitals (4.1 percent) had a reported number of CLABSI s that was significantly worse than predicted. These hospitals are listed below in Table 4.4.6 in alphabetical order and are designated in red in Figures 4.4.3 – 4.4.7. All other hospitals are considered to have an incidence of CLABSI s in their critical care units and ward locations that are within (or no different from) the number of infection predicted based on statewide rates of CLABSI s.

Among the other CLABSI-related locations (NICU, SCA and LTAC), two facilities with specialty care areas and one facility with a long-term acute care facility reported more CLABSI s than predicted. No NICUs had an observed number of infections that was significantly worse than predicted. Among 23 specialty care areas, the observed number of infections was significantly better than predicted in three hospitals (13.0 percent) and significantly worse than predicted in two hospitals (8.7 percent). Among 23 long term-acute care hospitals, there was three (13.0 percent) facilities that had an observed number of infections that was significantly better than predicted and one (4.3 percent) that was significantly worse than predicted.

Tables 4.4.8–4.4.11 list CLABSI rates and the predicted number of infections for ICUs and other wards, NICUs, SCAs and LTACs in alphabetical order by facility. In order to categorize and compare hospitals that are similar, Figures 4.4.3–4.4.12 divide the hospitals based on the reporting location (e.g., ICUs and other wards) and the number of predicted infections. Within each tier, hospitals are listed in order by SIR from best to worst.

Table 4.4.5: Hospitals with Significantly Fewer Central Line-Associated Bloodstream Infections (CLABSIs) than Predicted (Better = Smaller SIR) — Pennsylvania, 2015

	Hospital Name (NHSN ID)
<b>ICUs and other wards</b>	CONEMAUGH MEMORIAL MEDICAL CENTER (10280) PINNACLE HEALTH HOSPITALS - HARRISBURG HOSPITAL (34068) PINNACLE HEALTH HOSPITALS - WEST SHORE HOSPITAL (35123) ST. CLAIR MEMORIAL HOSPITAL (10561)

## 4.5 Surgical site infections (SSIs)

Surgical site infections (SSIs) are those HAIs that occur in association with an inpatient operation that involves at least one skin incision and complete closure of the incision site before the patient leaves the operating theater.

Pennsylvania data show that SSIs are the second most common category of HAIs in 2015, exceeded for the first time by GI infections. This is likely due to changes in the *C. difficile* case definition.

SSIs are a substantial problem in the hospital, as they are very costly, are linked to excess deaths, increase the length of hospitalization, lead to hospital readmissions and produce long-term consequences. There is a growing body of evidence that SSIs can be prevented through the use of science-based measures. These include the use of peri-operative prophylactic antibiotics, preparation of the surgical site (especially hair removal techniques and pre-operative skin disinfection) and post-operative wound care. A number of factors have been associated with the likelihood an SSI will develop. These include the type of surgical procedure, the underlying health status of the patient, whether the procedure is done emergently or electively, the condition and circumstances of the operative site (e.g., the cleanliness of the wound), duration of the surgical procedure, and the surgeon who performs the procedure.

### 4.5.1 SSIs — Statewide Summary

For each procedure type, the total number of hospitals performing that procedure is shown in Table 4.5.1. As discussed in the methods, direct comparison of rates before and after 2012 are complicated by changes in the follow-up surveillance period in 2012 and the inclusion of colon surgeries as a seventh benchmarked procedure in 2013. In addition, the infection rates for some SSI types (e.g., cardiac bypass graft surgery with one incision) have varied significantly from year-to-year, whereas, the rate point-estimates appear to be somewhat more stable for benchmarked procedures performed more frequently (e.g., knee prosthesis and hip prosthesis).

Table 4.5.1 shows the SSI rate for each of the seven procedure types performed in 2015, rates for previous years and the percent change. The rates of infection for procedures performed in 2015 ranged from a low of 0.59 SSIs per 100 knee arthroplasties to a high of 5.30 per 100 SSIs per 100 colon (COLO) surgeries. When interpreting this table for potential trends, one must exercise caution, as the change in surveillance period during this time and the addition of colon surgeries as a benchmarked procedure needs to be accounted for. See previous reports for a detailed discussion of these limitations. Nonetheless, statewide rates of infection have decreased dramatically since 2009 for some surgery types; the rate of infection after a hip prosthesis, abdominal hysterectomy, knee prosthesis or cardiac surgery decreased 10.4, 20.4, 36.3 and 46.6 percent, respectively.

Table 4.5.1: Summary of Reporting Hospitals and Surgical Site Infections (SSIs) by Benchmarked Procedure and Year — Pennsylvania, 2009–2015

				Unadjusted (Crude)	Change in Rate Since Prior Year	Change in Rate Since Baseline

#### 4.5.2 SSIs — By Pathogen

Table 4.5.2 shows the pathogen data for surgical site infections resulting from procedures performed in 2013 through 2015. Pathogens isolated in 1 percent or more of all SSIs are listed individually. Pathogens isolated in less than 1 percent of SSIs have been included in the table as "Other." The number of pathogens is not broken down by procedure type, as the number of SSIs is small for individual procedure categories; however, *S. aureus* was the most commonly reported pathogen in each procedure category. The total number of isolated pathogens is greater than the number of SSIs, as NHSN allows for reporting of more than one pathogen per infection.

Table 4.5.2: Pathogens Isolated from Surgical Site Infections — Pennsylvania, 2013–2015

Pathogen	2013		2014		2015	
	Count	%	Count	%	Count	%
<i>Staphylococcus aureus</i>	480	20.70	494	20.52	486	20.05
<i>Escherichia coli</i>	348	15.01	353	14.67	336	13.86

All	2,319	100.00	2,407	100.00	2,424	100.00

#### **4.5.3 SSIs — Risk-Adjusted Rates**

Since information is collected on all patients undergoing the benchmark operative procedures, it is possible to calculate SSI rates for patient characteristics that are used for SSI risk adjustment purposes. For this report, rates are adjusted by the risk index. The risk index is comprised of:

- American Society of Anesthesiology (ASA) score (a measure of the overall health of the patient);
- Wound classification (clean vs. unclean); and
- Operative duration (below or above the median).

Each patient is assigned a risk index (RI) score of 0 to 3, with a possible single point given for each of the three criteria. For instance, a patient with a low ASA score (meaning they are a low-risk patient for surgical complications — i.e., they are in good health), a clean wound and a short operative duration would have a risk index of 0. A patient with a high ASA score (a person at high risk of surgical complications due to poor health), a contaminated operative site and long procedure duration would have a risk index score of 3. Patients can therefore have an assigned risk index of 0, 1, 2 or 3 based on whether or not a point is assigned for each factor that comprises the risk index.

Table 4.5.3 demonstrates the SSI rate for each benchmark procedure by risk index category for 2015. Studies have shown that, in general, the SSI rate increases in concert with an increasing risk index. In general, this is true for the seven benchmark procedures in Pennsylvania. However, as shown in Table 4.5.3, this is not always the case. This usually results because the number of procedures and/or SSIs in some of the risk index strata is small. For instance, in 2015, only 18 cardiac bypass (two incisions) procedures were done on patients with a risk index of 0, and a similar small number (9 procedures) were done on patients with a risk index of 3.

To determine the risk-adjusted SIR for each hospital, the hospital's SSI rate for each risk index category (e.g., for their patients with a risk index of 0, 1, 2, and 3) is compared to the overall statewide rate for each risk index stratum. The number of predicted SSIs for each hospital is calculated based on the number of procedures they reported performing within each risk index category and the statewide rate for that stratum. The predicted number is then compared to the observed number. This is done for each risk index category to produce an overall predicted SSI number, and this is compared to the overall observed number to produce the risk adjusted SIR for each procedure. As with CAUTIs and CLABSIs, the confidence interval (CI) is then calculated to determine if the number of SSIs reported by the hospital is significantly better or worse than predicted, in comparison to the statewide rate. Hospitals with significantly better or worse than predicted SIRs are found in Tables 4.5.6–4.5.7.

Table 4.5.3: Surgical Site Infections and Crude Infection Rate by Benchmarked Procedure and Risk Index — Pennsylvania, 2015

	Risk Index	Number of SSIs	Number of Procedures	Crude Rate per 100 Procedures
Cardiac (CARD)	0	0	100	0.00
	1	44	6,733	0.65
	2	11	1,803	0.61
	3	1	39	2.56

#### 4.5.4 SSIs — By Procedure Type and Facility

The SIRs for each of the benchmarked procedures by hospital are presented in Tables 4.5.8–4.5.13. In these tables, the hospitals are listed sequentially from fewest to most predicted SSIs. Table 4.5.15 presents the same information in alphabetical order by hospital. This enables the reader to review and compare a specific hospital's SIRs for each procedure.

### **Cardiac surgical procedures :**

As shown in Table 4.5.4, among the 70 hospitals that performed cardiac surgery in 2015, the median number of reported SSIs was 0. In that year, 46 (65.7 percent) of these hospitals reported no cardiac surgery-related SSIs, and 54 (77 percent) had a predicted number of infections that was  $<1.00$ . Information regarding hospitals with  $<1$  predicted cardiac surgical site infection is considered statistically unreliable (as evidenced by the extremely wide confidence intervals in the tables for these facilities). During 2015, 51 (72.9 percent) of the hospitals performing cardiac surgery had an adjusted SIR that was  $<1.00$  (meaning the number of reported cardiac surgery-related SSIs was lower than predicted), while the remaining 19 (27.1 percent) had an SIR  $\geq 1.00$  (the number reported was higher than predicted). Table 4.5.7 includes one (1.4) hospital which had a significantly worse SIR than predicted. Facility-specific rates are found in Table 4.5.8.

### **Cardiac bypass graft — single incision procedures (CBGC) :**

As shown in Table 4.5.4, among the 59 hospitals that reported performing single (chest) incision cardiac bypass grafts (CBGC) in 2015, the median number of post-surgical SSIs was 0, and only 13 (22.0 percent) of the hospitals reported any CBGC-related SSIs. The remaining 46 (78.0 percent) reported none. In addition, 47 (79.7 percent) of the hospitals had  $<1$  predicted infection in the CBGC category; for these hospitals, the findings are considered to be statistically unreliable. Among all hospitals performing CBGCs in 2015, 47 (79.7 percent) of the hospitals performing CBGCs had a reported number of SSIs that was less than predicted (an SIR  $<1.00$ ), and only 12 (20.3 percent) reported more SSIs (an SIR  $>1.00$ ) than predicted; none had significantly better or worse SIRs than predicted (Table 4.5.7), while one (1.7 percent) had a significantly worse SIR than predicted. This hospital is listed in Table 4.5.7.

### **Cardiac bypass graft — two incision procedures (CBGB) :**

As shown in Table 4.5.4, among the 62 hospitals that performed two-incision (chest and donor site) cardiac bypass grafts in 2015, the median number of SSIs was 2, and 19 (30.6 percent) reported no CBGB-related SSIs. Among these hospitals, only 12 (19 percent) had  $<1$  predicted infection. In 2015, there were 34 (54.8 percent) hospitals performing CBGBs that had a lower number of SSIs than predicted (their adjusted SIR was  $<1.00$ ), while 28 (45.2 percent) had a greater or equal to number of SSIs than predicted (SIR  $\geq 1.00$ ). Among the 62 hospitals, one (2 percent) reported significantly fewer infections than predicted (listed in Table 4.5.6), while two hospitals (3.2 percent) reported significantly more infections than predicted; these hospitals are listed in Table 4.5.7.

### **Knee prostheses (KPRO) :**

As shown in Table 4.5.4, among the 156 hospitals performing knee arthroplasties (prostheses) in 2015, the median number of SSIs was 1; a total of 59 (37.8 percent) reported no SSIs in this procedure category. Among the 156 hospitals, 73 (47 percent) had a predicted number of infections that was  $<1$ ; for these hospitals, the findings are considered statistically unreliable. Among hospitals performing knee arthroplasties in 2015, there were 93 (59.6 percent) that had a fewer number (SIR  $<1.00$ ) of knee prosthesis-related SSIs reported than predicted; two hospitals (1 percent) had a significantly lower SIR (better) than predicted. The remaining 63 (40.4 percent) had a greater or equal number (SIR  $\geq 1.00$ ) of SSIs reported than predicted; two (1.3 percent) hospitals had a significantly higher number of SSIs reported than were predicted in that year. The hospitals with a significantly lower than, and higher than, predicted number of knee procedure-related surgical site infections can be found in Tables 4.5.6 and 4.5.7.

### **Hip prostheses (HPRO) :**

As shown in Table 4.5.4, among the 161 hospitals performing hip arthroplasties (prostheses) in 2015, the median number of SSIs was 1; a total of 65 (40.4 percent) reported no SSIs in this procedure category, and 65 (40 percent) had a predicted number of infections that was  $<1$  (meaning the findings for these hospitals are statistically unreliable). Among hospitals performing hip arthroplasties in 2015, there were 101 (62.7 percent) that had a fewer number (SIR

$<1.00$ ) of SSIs reported than predicted; among these hospitals, two (1 percent) had a significantly lower number of infections reported than predicted. The remaining 60 (37.3 percent) had a greater or equal number ( $SIR \geq 1.00$ ) of SSIs reported than predicted; among these hospitals, eight had a significantly higher (or worse) number of hip prosthesis-related SSIs than predicted. The hospitals with a significantly better or worse number of infections than predicted can be found in Tables 4.5.6 and 4.5.7.

#### **Abdominal hysterectomies (HYST) :**

As shown in Table 4.5.4, among the 142 hospitals performing abdominal hysterectomies in 2015, the median number of SSIs was 0, and there were 74 (52.1 percent) that reported no SSIs associated with this procedure and 87 (61 percent) with a predicted number of SSIs that was  $<1$  (the findings for hospitals with  $<1$  predicted infection are considered statistically unreliable). Among hospitals who performed abdominal hysterectomies in 2015, a total of 91 (64.1 percent) hospitals reported fewer SSIs than predicted ( $SIR <1.00$ ), while the other 51 (35.9 percent) reported more or equal SSIs than predicted ( $SIR \geq 1.00$ ). Two hospitals (1 percent) had a significantly lower number of SSIs than predicted, and six (4.2 percent) hospitals had a significantly higher number of SSIs than predicted. These hospitals can be found in Tables 4.5.6 and 4.5.7.

**Colon surgeries (COLO) :** As shown in Table 4.5.4, among the 157 hospitals performing colon surgeries in 2015, the median number of SSIs was 3; a total of 35 (22.3 percent) reported no SSIs in this procedure category, and 30 (19 percent) had a predicted number of infections that was  $<1$  (meaning the findings for these hospitals are statistically unreliable). Among hospitals performing colon surgeries in 2015, there were 101 (64.3 percent) that had a fewer number ( $SIR <1.00$ ) of SSIs reported than predicted; among these hospitals, twelve (8 percent) had a significantly lower number of infections reported than predicted. The remaining 56 (35.7 percent) had a greater or equal number ( $SIR \geq 1.00$ ) of SSIs reported than predicted; among these hospitals, eight had a significantly higher (or worse) number of SSIs than predicted. The hospitals with a significantly better or worse number of infections than predicted can be found in Tables 4.5.6 and 4.5.7.

## **4.6 Influenza Vaccination of Health Care Providers (HCP)**

Vaccination of HCP against influenza is an important indicator and measure of institutional commitment to patient safety. Influenza vaccination is the single most effective way of preventing influenza. Influenza vaccination keeps HCP healthy, protects their families and likely reduces the risk of transmission in health care settings. Vaccinating HCP against influenza protects patients by not exposing them to infected personnel, decreasing absenteeism, and promoting a healthy workforce to care for those who tend to be most at risk. Initiatives to promote universal influenza vaccination for HCP are strongly encouraged for all hospitals in Pennsylvania to achieve the Healthy People 2020 goal of at least 90 percent coverage.

PADOH published hospital HCP influenza vaccination rates in aggregate in the 2011 annual report and has published facility-specific vaccination rates since then to promote awareness and provide a statewide baseline for this important measure of institutional commitment to patient safety. Act 52 does not require hospitals to provide this information. However, federal initiatives and changes to Joint Commission Accreditation Standards make it critical for health care institutions to have effective health care personnel influenza vaccination programs in place:

1. Health care personnel influenza vaccination rates are now tied to Medicare reimbursement. On Aug. 18, 2011, the Centers for Medicare and Medicaid Services (CMS) published a final rule requiring acute care hospitals to report health care personnel influenza vaccination rates through NHSN. Fiscal year 2015 payments under Medicare's inpatient prospective payment system (IPPS) will be reduced by 2 percent if acute care hospitals fail to report required quality measures starting in January 2013. Quality data also are made publicly available on CMS's Hospital Compare website.
2. The Joint Commission (JC) has issued accreditation standards to encourage influenza vaccination rates among health care personnel to achieve vaccination of health care personnel of 90 percent or better. In addition to hospitals (including critical access hospitals), these standards apply to ambulatory, behavioral, home care, laboratory, long-term care and office-based surgery facilities.  
[http://www.jointcommission.org/ic020401\\_CAH\\_HAP\\_LTC/](http://www.jointcommission.org/ic020401_CAH_HAP_LTC/)

This is the fourth year that PADOH is publishing facility-specific HCP vaccination rates. These rates are based on data submitted by facilities to NHSN. The NHSN assessment of HCP vaccination rates is based on National Quality Forum (NQF) Metric 0431. Reporting of contractor vaccination rates to NHSN is possible but optional and not necessary to qualify for full CMS pay-for-reporting incentives. Please refer to the following resources for a detailed description of the assessments:

<http://www.cdc.gov/nhsn/faqs/FAQ-Influenza-Vaccination-Summary-Reporting.html>

### **4.6.1 Influenza Vaccination of HCP — Statewide Summary**

All 254 hospitals open during the 2015–2016 influenza season reported healthcare personnel influenza vaccination rates to NHSN (including three hospitals that opened part way through the season), and 175 hospitals (69 percent) reported vaccination rates for contractors in addition to vaccination rates for employees, licensed independent practitioners (LIP), and adult students, trainees and volunteers (STV). Overall, hospitals reported the vaccination status of 409,601 HCP (see Table 4.6.1; individual HCP might be represented in the numerator and denominator data reported by multiple facilities if the HCP worked in more than one NHSN facility during the influenza season).

Facilities have continued to build systems for effectively tracking HCP influenza vaccination rates. The median

facility HCP unknown vaccination rate is near zero for the 2015–2016 influenza season. Notably, the median facility unknown vaccination rate among LIPs decreased from 10.7 percent to 5.3 percent. Consistent with previous data, less than 0.01 percent of HCP were not vaccinated because of a reported medical contraindication to influenza vaccine.

Table 4.6.1: Summary of Healthcare Personnel Influenza Vaccination Rates (Median Facility Percentage) During the 2015–2016 Influenza Season — Pennsylvania

	Vaccinated		Declined		Medical Contraindication		Unknown	
	n	median %	n	median %	n	median %	n	median %
Employee	279,787	93.77	14,322	2.89	2,204	0.62	9,254	0.56
LIP <sup>b</sup>	41,673	87.45	944	0.00	458	0.00	13,252	5.33
STV <sup>c</sup>	58,213	97.18	1,831	0.00	152	0.00	3,806	0.00
Contractor	9,666	97.68	305	0.00	46	0.00	989	0.00
All	389,339	94.24	17,402	0.23	2,860	0.00	27,301	0.00

<sup>a</sup> Individual HCP might be represented in the numerator and denominator data reported by multiple facilities if the HCP worked in more than one NHSN facility during the influenza season. Rates are the median facility vaccination rate.

<sup>b</sup> Licensed independent practitioner

<sup>c</sup> Student, trainee, volunteer

#### 4.6.2 Influenza Vaccination of HCP — By Facility

Hospitals reported significant improvements from last year. The median employee vaccination rate increased 5 percent (from 89 percent to 94 percent) from the 2014–2015 season to the 2015–2016 influenza season. Many facilities achieved HCP vaccination rates at or above the Healthy People 2020 goal of 90 percent, as indicated by the green bars in Figure 4.6.1. For the 2015–2016 influenza season, 152 facilities (60 percent of 254 facilities) reported employee vaccination rates above 90 percent, and 71 facilities (28 percent) reported vaccination rates at goal for employees, LIPs and STVs; this is an increase of 27 percent and 42 percent respectively from the previous season. Overall, the percent of facilities with employee vaccination rates at goal has increased 245 percent since the 2011–2012 influenza season. Facilities achieving employee vaccination rates above 90 percent are listed in alphabetical order in Table 4.6.2; those facilities with vaccination rates above 90 percent for employees, LIPs and STVs are noted with an asterisk.

Vaccination rates continue to vary substantially between facilities; however, unlike the bimodal distribution of facility vaccination rates of the 2011–2012 and 2012–2013 influenza seasons, the distribution of influenza vaccination rates is becoming increasingly skewed with 60 percent of all facilities at or above goal and a long tail of facilities below goal (Figure 4.6.1). Among the 152 facilities with employee vaccination rates of 90 percent or better, the median employee vaccination rate was 97 percent, whereas the median employee vaccination rate among facilities not yet at goal was 72 percent.

Among the 25 largest facilities in the state (tenth decile by bed size; Figure 4.6.2), 19 (76 percent) reported all-HCP vaccination rates above 90 percent; three facilities reported a rate between 80 and 90 percent; and the remaining three facilities reported all-HCP vaccination rates between 41 and 78 percent. Figure 4.6.3 is a map of the approximate location of each hospital; the color of the mapped hospital indicates its employee vaccination rate. Notably, the number of facilities at goal in western Pennsylvania increased substantially from last year. Table 4.6.3 lists HCP seasonal influenza vaccination rates by facility.

Among the 26 smallest facilities (i.e., smallest decile by bed size) rates were more widely distributed; 14 facilities reported all-HCP vaccination rates above 90 percent, four facilities reported rates between 80 and 90 percent, four reported rates between 60 and 80 percent and four facilities reported rates between 40 and 60 percent. Table 4.6.3 lists HCP seasonal influenza vaccination rates by facility.

## 5 Conclusion

The 2015 report is the eighth report published by PADOH since reporting was mandated by the 2007 amendment to the MCARE Act. This report, like previous reports, demonstrates the significant progress and enduring commitment made by hospitals in Pennsylvania to reduce HAIs.

Hospitals have demonstrated particular success in reducing the use of urinary catheters and central lines, decreasing the proportion of HAIs attributable to MRSA, preventing KPRO, HPRO, HYST and CARD SSIs and preventing and improving influenza vaccination rates among health care personnel (245 percent increase since 2011–2012 influenza season).

It has been estimated (Scott, 2009) that the average cost of any type of HAI is between \$14,000 – \$15,000, considering only direct medical costs. HAIs such as bloodstream infections and surgical site infections are known to be much costlier. Using conservative estimates, the reductions seen over the last four years in Pennsylvania have saved an estimated minimum of \$150 million in direct health care costs that would have been associated with those HAIs.

The reductions seen in Pennsylvania are the result of a concerted effort on the part of the infection prevention community to address the problem of HAIs. Some of the factors that have contributed to the favorable trends are the increased spotlight on HAIs by the public; public reporting of data; implementation of prevention strategies by infection preventionists, health care providers and health care systems; participation in prevention collaboratives; increased scrutiny by hospital administration; and federal efforts to link incentive payments to successful control of HAIs.

As seen throughout this report, there is significant variation in the rates of HAIs among the 251 hospitals in Pennsylvania. The major reason for these differences is the wide variation in the type of care being provided, the intensity of care and the patient population being served. Larger tertiary referral centers would be expected to provide more intensive care for sicker patients who are at greater risk for developing an HAI. The analyses presented in this report recognize these differences through the use of risk adjustments methods for the CAUTI, CLABSI and SSI standardized infection ratios. However, these risk adjustment methods are imperfect and cannot fully account for all of these differences between hospitals. It is important to keep this in mind when using the information contained in this report. The HAI rate is only one factor that should be used when making decisions about where to receive health care; it should not necessarily be construed that hospitals with higher rates or SIRs provide "worse" care and hospitals with lower rates and SIRs provide "better" care.

The section of the 2015 report dealing with health care personnel influenza vaccination provides an alternative metric in measuring hospital commitment to patient safety and HAI prevention. The median employee influenza vaccination rate was 94 percent and 152 facilities (60 percent) achieved employee vaccination rates of 90 percent or better, a 2020 Healthy People goal, during the 2015–2016 influenza season. This is a dramatic 245 percent improvement from baseline data. The number of facilities at goal for employees, licensed independent practitioners, and students, trainees and volunteers increased from 6 to 71 since the 2011–2012 influenza season. This is a 1083 percent improvement! There is widespread agreement in the health care community that health care workers ought to be vaccinated against influenza to protect their own health and to protect the health of their patients. Vaccination also decreases absenteeism (up to 30 percent in some studies) and preserves surge capacity during flu season. Universal influenza vaccination of the health care workforce (generally defined as 90 percent or better vaccination coverage) is endorsed by major medical organizations and federal recommendations. These improvements are the result of collaboration between facilities and stakeholders across the state, sharing of best practices and strong leadership within facilities.

Despite these notable achievements among many facilities, HCP vaccination rates are still significantly below goal for other facilities. The hospitals with the highest vaccination coverage have done so through mandatory vaccination policies as a condition of employment. This policy is the only one that has been shown to consistently result in high levels of vaccination (often greater than 97 percent coverage; Talbot *et al.*, 2010). Other methods can also be successful, but generally require a great deal of effort to promote vaccination and encourage personnel to receive the vaccine; they have also been difficult to sustain over time. Hospitals are encouraged to consider mandatory vaccination policies in order to achieve the Healthy People 2020 goal. The Pennsylvania Department of Health will continue to publish HCP influenza vaccination rates in this report, and the Centers for Medicaid

and Medicare Services will be publishing HCP influenza vaccination rates on the CMS Hospital Compare Website (<https://data.medicare.gov/data/hospital-compare>) for those facilities that receive reimbursement for services through the Inpatient Prospective Payment System.

The Department of Health will continue to work with its partner agencies, the Patient Safety Authority, the Pennsylvania Health Care Cost Containment Council, outside organizations and the infection prevention community to collect data on the occurrence of HAIs and to recommend methods to reduce their occurrence. An important role is to continue to validate the accuracy of data submitted by the hospitals to assure the accuracy of the reported rates and standardized infection ratios. This will be done through continuous inspection of the submitted reports and through on-site validation as resources permit. PADOH is committed to ensuring useful and usable data on HAIs for the health care community and the public. The information can then be used by all stakeholders to continue to reduce the occurrence of HAIs with a goal of eventually eliminating them.
